

# Week 03b: Search Tree Data Structures

## Searching

1/49

An extremely common application in computing

- given a (large) collection of *items* and a *key* value
- find the item(s) in the collection containing that key
  - item = (key, val<sub>1</sub>, val<sub>2</sub>, ...) (i.e. a structured data type)
  - key = value used to distinguish items (e.g. student ID)

Applications: Google, databases, .....

## ... Searching

2/49

Since searching is a very important/frequent operation, many approaches have been developed to do it

Linear structures: arrays, linked lists, files

Arrays = random access. Lists, files = sequential access.

Cost of searching:

<https://tutorcs.com>

	Array	List	File
Unsorted	$O(n)$ (linear scan)	$O(n)$ (linear scan)	$O(n)$ (linear scan)
Sorted	$O(\log n)$ (binary search)	$O(n)$ (linear scan)	$O(\log n)$ ( <i>seek, seek&gt;, ...</i> )

- $O(n)$  ... linear scan (search technique of last resort)
- $O(\log n)$  ... binary search, *search trees* (trees also have other uses)

Also (cf. COMP9021): hash tables ( $O(1)$ , but only under optimal conditions)

## ... Searching

3/49

Maintaining the order in sorted arrays and files is a costly operation.

*Search trees* are as efficient to search but more efficient to maintain.

Example: the following tree corresponds to the sorted array [2, 5, 10, 12, 14, 17, 20, 24, 29, 30, 31, 32]:

## Tree Data Structures

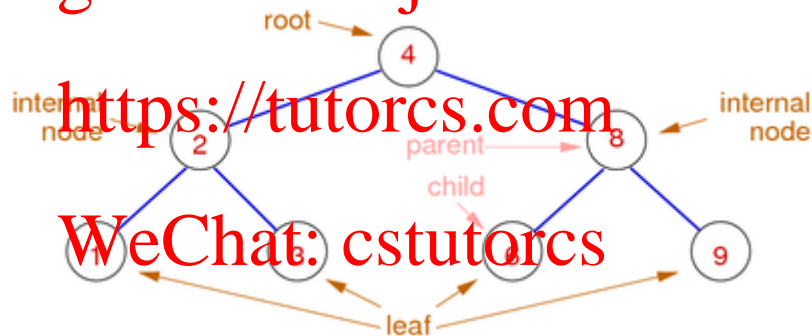

### Trees

5/49

*Trees* are connected graphs

- consisting of nodes and edges (called *links*), with no cycles (no "up-links")
- each node contains a **data** value (or key+data)
- each node has **links** to  $\leq k$  other child nodes ( $k=2$  below)

## Assignment Project Exam Help

### ... Trees

6/49

Trees are used in many contexts, e.g.

- representing hierarchical data structures (e.g. expressions)
- efficient searching (e.g. sets, symbol tables, ...)

7/49

## ... Trees

Trees can be used as a data structure, but also for *illustration*.

E.g. showing evaluation of a prefix arithmetic expression

## ... Trees

8/49

Binary trees ( $k=2$  children per node) can be defined recursively, as follows:

A *binary tree* is either

- empty (contains no nodes)
- consists of a *node* with two *subtrees*
  - node contains a value
  - left and right subtrees are *binary trees*

<https://tutorcs.com>  
WeChat: cstutorcs

## ... Trees

9/49

Other special kinds of tree

- *m-ary tree*: each internal node has exactly  $m$  children
- *Ordered tree*: all left values  $<$  root, all right values  $>$  root
- *Balanced tree*: has  $\cong$  minimal height for a given number of nodes
- *Degenerate tree*: has  $\cong$  maximal height for a given number of nodes

## Search Trees

10/49

# Binary Search Trees

*Binary search trees* (or *BSTs*) have the characteristic properties

- each node is the root of 0, 1 or 2 subtrees
- all values in any left subtree are less than root
- all values in any right subtree are greater than root
- these properties applies over all nodes in the tree

*perfectly balanced trees* have the properties

- #nodes in left subtree = #nodes in right subtree
- this property applies over all nodes in the tree

## ... Binary Search Trees

# Assignment Project Exam Help

12/49

Operations on BSTs:

- `insert(Tree, Item)` ... add new item to tree via key
- `delete(Tree, Key)` ... remove item with specified key from tree
- `search(Tree, Key)` ... find item containing key in tree
- plus, "bookkeeping" ... `new()`, `free()`, `show()`, ...

Notes:

- in general, nodes contain `Items`; we just show `Item.key`
- keys are unique (not technically necessary)

## ... Binary Search Trees

13/49

Examples of binary search trees:

Shape of tree is determined by order of insertion.

## ... Binary Search Trees

14/49

*Level* of node = path length from root to node

*Height* (or: *depth*) of tree = max path length from root to leaf

*Height-balanced tree*:  $\forall$  nodes:  $\text{height}(\text{left subtree}) = \text{height}(\text{right subtree})$

Time complexity of tree algorithms is typically  $O(\text{height})$

## Exercise #1: Insertion into BSTs

15/49

For each of the sequences below

- start from an initially empty binary search tree
- show tree resulting from inserting values in order given

(a) 4 2 6 5 1 7 3

(b) 6 5 2 3 4 7 1

(c) 1 2 3 4 5 6 7

Assume new values are always inserted as new leaf nodes

(a) the balanced tree from 3 slides ago (height = 2)

(b) the non-balanced tree from 3 slides ago (height = 4)

(c) a fully degenerate tree of height 6

## Representing BSTs

17/49

Binary trees are typically represented by node structures

- containing a value, and pointers to child nodes

Most tree algorithms move *down* the tree.

If upward movement needed, add a pointer to parent.

## ... Representing BSTs

18/49

Typical data structures for trees ...

```
// a Tree is represented by a pointer to its root node
typedef struct Node *Tree;
```

```
// a Node contains its data, plus left and right subtrees
typedef struct Node {
    int data;
    Tree left, right;
} Node;
```

```
// some macros that we will use frequently
#define data(tree) ((tree)->data)
#define left(tree) ((tree)->left)
#define right(tree) ((tree)->right)
```

We ignore items  $\Rightarrow$  data in Node is just a key

 WeChat: cstutorcs

## ... Representing BSTs

19/49

Abstract data vs concrete data ...

## Tree Algorithms

## Searching in BSTs

21/49

## Most tree algorithms are best described recursively

`TreeSearch(tree, item):`

```

Input  tree, item
Output true if item found in tree, false otherwise

if tree is empty then
    return false
else if item < data(tree) then
    return TreeSearch(left(tree), item)
else if item > data(tree) then
    return TreeSearch(right(tree), item)
else
    // found
    return true
end if

```

---

## Insertion into BSTs

22/49

Insert an item into appropriate subtree

`insertAtLeaf(tree, item):`

```

Input  tree, item
Output tree with item inserted

if tree is empty then
    return new node containing item
else if item < data(tree) then
    return insertAtLeaf(left(tree), item)
else if item > data(tree) then
    return insertAtLeaf(right(tree), item)
else
    return tree // avoid duplicates
end if

```

## Tree Traversal

23/49

Iteration (traversal) on ...

- Lists ... visit each value, from first to last
- Graphs ... visit each vertex, order determined by DFS/BFS/...

For binary Trees, several well-defined visiting orders exist:

- *preorder* (NLR) ... visit root, then left subtree, then right subtree
  - *inorder* (LNR) ... visit left subtree, then root, then right subtree
  - *postorder* (LRN) ... visit left subtree, then right subtree, then root
  - *level-order* ... visit root, then all its children, then all their children
- 

## ... Tree Traversal

24/49

Consider "visiting" an expression tree like:

NLR: + \* 1 3 - \* 5 7 9 (prefix-order: useful for building tree)  
 LNR: 1 \* 3 + 5 \* 7 - 9 (infix-order: "natural" order)  
 LRN: 1 3 \* 5 7 \* 9 - + (postfix-order: useful for evaluation)  
 Level: + \* - 1 3 \* 9 5 7 (level-order: useful for printing tree)

## Exercise #2: Tree Traversal

25/49

Show NLR, LNR, LRN traversals for the tree

Assignment Project Exam Help

<https://tutorcs.com>

NLR (preorder): 20 10 5 2 14 12 17 30 24 29 32 31

LNR (inorder): 2 5 10 12 14 17 20 24 29 30 31 32

LRN (postorder): 2 5 12 17 14 10 29 24 31 32 30 20

## Exercise #3: Non-recursive traversals

27/49

Write a non-recursive *preorder* traversal algorithm.

Assume that you have a stack ADT available.

```

showBSTreePreorder(t):
    Input tree t

    push t onto new stack S
    while stack is not empty do
        t=pop(S)
        print data(t)
        if right(t) is not empty then
            push right(t) onto S
        end if
        if left(t) is not empty then

```

```

|   |   push left(t) onto S
|   |   end if
|   end while

```

## Joining Two Trees

29/49

An auxiliary tree operation ...

Tree operations so far have involved just one tree.

An operation on two trees:  $t = \text{joinTrees}(t_1, t_2)$

- Pre-conditions:
  - takes two BSTs; returns a single BST
  - $\max(\text{key}(t_1)) < \min(\text{key}(t_2))$
- Post-conditions:
  - result is a BST (i.e. fully ordered)
  - containing all items from  $t_1$  and  $t_2$

### ... Joining Two Trees

30/49

Method for performing tree-join:

- find the min node in the right subtree ( $t_2$ )
- replace min node by its right subtree
- elevate min node to be new root of both trees

Advantage: doesn't increase height of tree significantly

$x \leq \text{height}(t) \leq x+1$ , where  $x = \max(\text{height}(t_1), \text{height}(t_2))$

Variation: choose deeper subtree; take root from there.

### ... Joining Two Trees

31/49

Joining two trees:

Note:  $t_2'$  may be less deep than  $t_2$

## ... Joining Two Trees

### Implementation of tree-join

```

joinTrees( $t_1, t_2$ ):
|   Input  trees  $t_1, t_2$ 
|   Output  $t_1$  and  $t_2$  joined together
|
|   if  $t_1$  is empty then return  $t_2$ 
|   else if  $t_2$  is empty then return  $t_1$ 
|   else
|       curr= $t_2$ , parent=NULL
|       while left(curr) is not empty do    // find min element in  $t_2$ 
|           parent=curr
|           curr=left(curr)
|       end while
|       if parent  $\neq$  NULL then
|           left(parent)=right(curr)  // unlink min element from parent
|           right(curr)= $t_2$ 
|       end if
|       left(curr)= $t_1$ 
|       return curr    // curr is new root
|   end if

```

### Exercise #4: Joining Two Trees

<https://tutorcs.com>

Join the trees

WeChat: cstutorcs

## Deletion from BSTs

Insertion into a binary search tree is easy.

Deletion from a binary search tree is harder.

Four cases to consider ...

- empty tree ... new tree is also empty

- zero subtrees ... unlink node from parent
- one subtree ... replace by child
- two subtrees ... replace by successor, join two subtrees

### ... Deletion from BSTs

36/49

Case 2: item to be deleted is a leaf (zero subtrees)

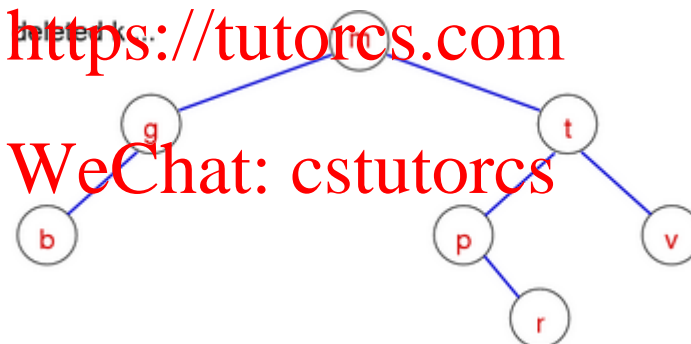

Just delete the item

### ... Deletion from BSTs

37/49

Case 2: item to be deleted is a leaf (zero subtrees)

### ... Deletion from BSTs

38/49

Case 3: item to be deleted has one subtree

Replace the item by its only subtree

39/49

## ... Deletion from BSTs

Case 3: item to be deleted has one subtree

## ... Deletion from BSTs

40/49

Case 4: item to be deleted has two subtrees

Version 1: right child becomes new root, attach left subtree to min element of right subtree

## ... Deletion from BSTs

WeChat: cstutorcs

41/49

Case 4: item to be deleted has two subtrees

## ... Deletion from BSTs

42/49

Case 4: item to be deleted has two subtrees

Version 2: *join* left and right subtree

## ... Deletion from BSTs

43/49

Case 4: item to be deleted has two subtrees

Assignment Project Exam Help

## ... Deletion from BSTs

44/49

<https://tutorcs.com>

Pseudocode (version 2 for case 4)

TreeDelete(t, item): WeChat: cstutorcs

```

Input  tree t, item
Output t with item deleted

if t is not empty then           // nothing to do if tree is empty
    if item < data(t) then        // delete item in left subtree
        left(t)=TreeDelete(left(t), item)
    else if item > data(t) then    // delete item in right subtree
        right(t)=TreeDelete(right(t), item)
    else                          // node 't' must be deleted
        if left(t) and right(t) are empty then
            new=empty tree        // 0 children
        else if left(t) is empty then
            new=right(t)          // 1 child
        else if right(t) is empty then
            new=left(t)           // 1 child
        else
            new=joinTrees(left(t), right(t)) // 2 children
        end if
        free memory allocated for t
        t=new
    end if
end if
return t
  
```

# Application of BSTs: Sets

Trees provide efficient search.

Sets require efficient search

- to find where to insert/delete
- to test for set membership

Logical to implement a set ADT via BSTree

## ... Application of BSTs: Sets

46/49

Assuming we have `Tree` implementation

- which precludes duplicate key values
- which implements insertion, search, deletion

then `Set` implementation is

- `SetInsert(Set, Item)  $\equiv$  TreeInsert(Tree, Item)`
- `SetDelete(Set, Item)  $\equiv$  TreeDelete(Tree, Item, Key)`
- `SetMember(Set, Item)  $\equiv$  TreeSearch(Tree, Item, Key)`

## ... Application of BSTs: Sets

47/49

WeChat: cstutorcs

After `SetInsert(s,4)`:

After `SetDelete(s,2)`:

## ... Application of BSTs: Sets

48/49

Concrete representation:

```
#include <BSTree.h>

typedef struct SetRep {
    int    nelems;
    Tree   root;
} SetRep;

typedef Set *SetRep;

Set newSet() {
    Set S = malloc(sizeof(SetRep));
    assert(S != NULL);
    S->nelems = 0;
    S->root = newTree();
    return S;
}
```

---

## Summary

49/49

- Binary search tree (BST) data structure
- Tree traversal
- Basic BST operation: insertion, join, deletion
